Architectural Principles for NASPINet

- Enable high performance
 - Low latency
 - Security
 - QoS
 - Flexibility and agility
- Use open standards; apply sound architectural principles
 - Allocate functionality to proper places in the architecture
 - Make maximum use of necessary elements
 - Avoid defining new system entities
- Provide upgrade and extension paths (future-proofing)

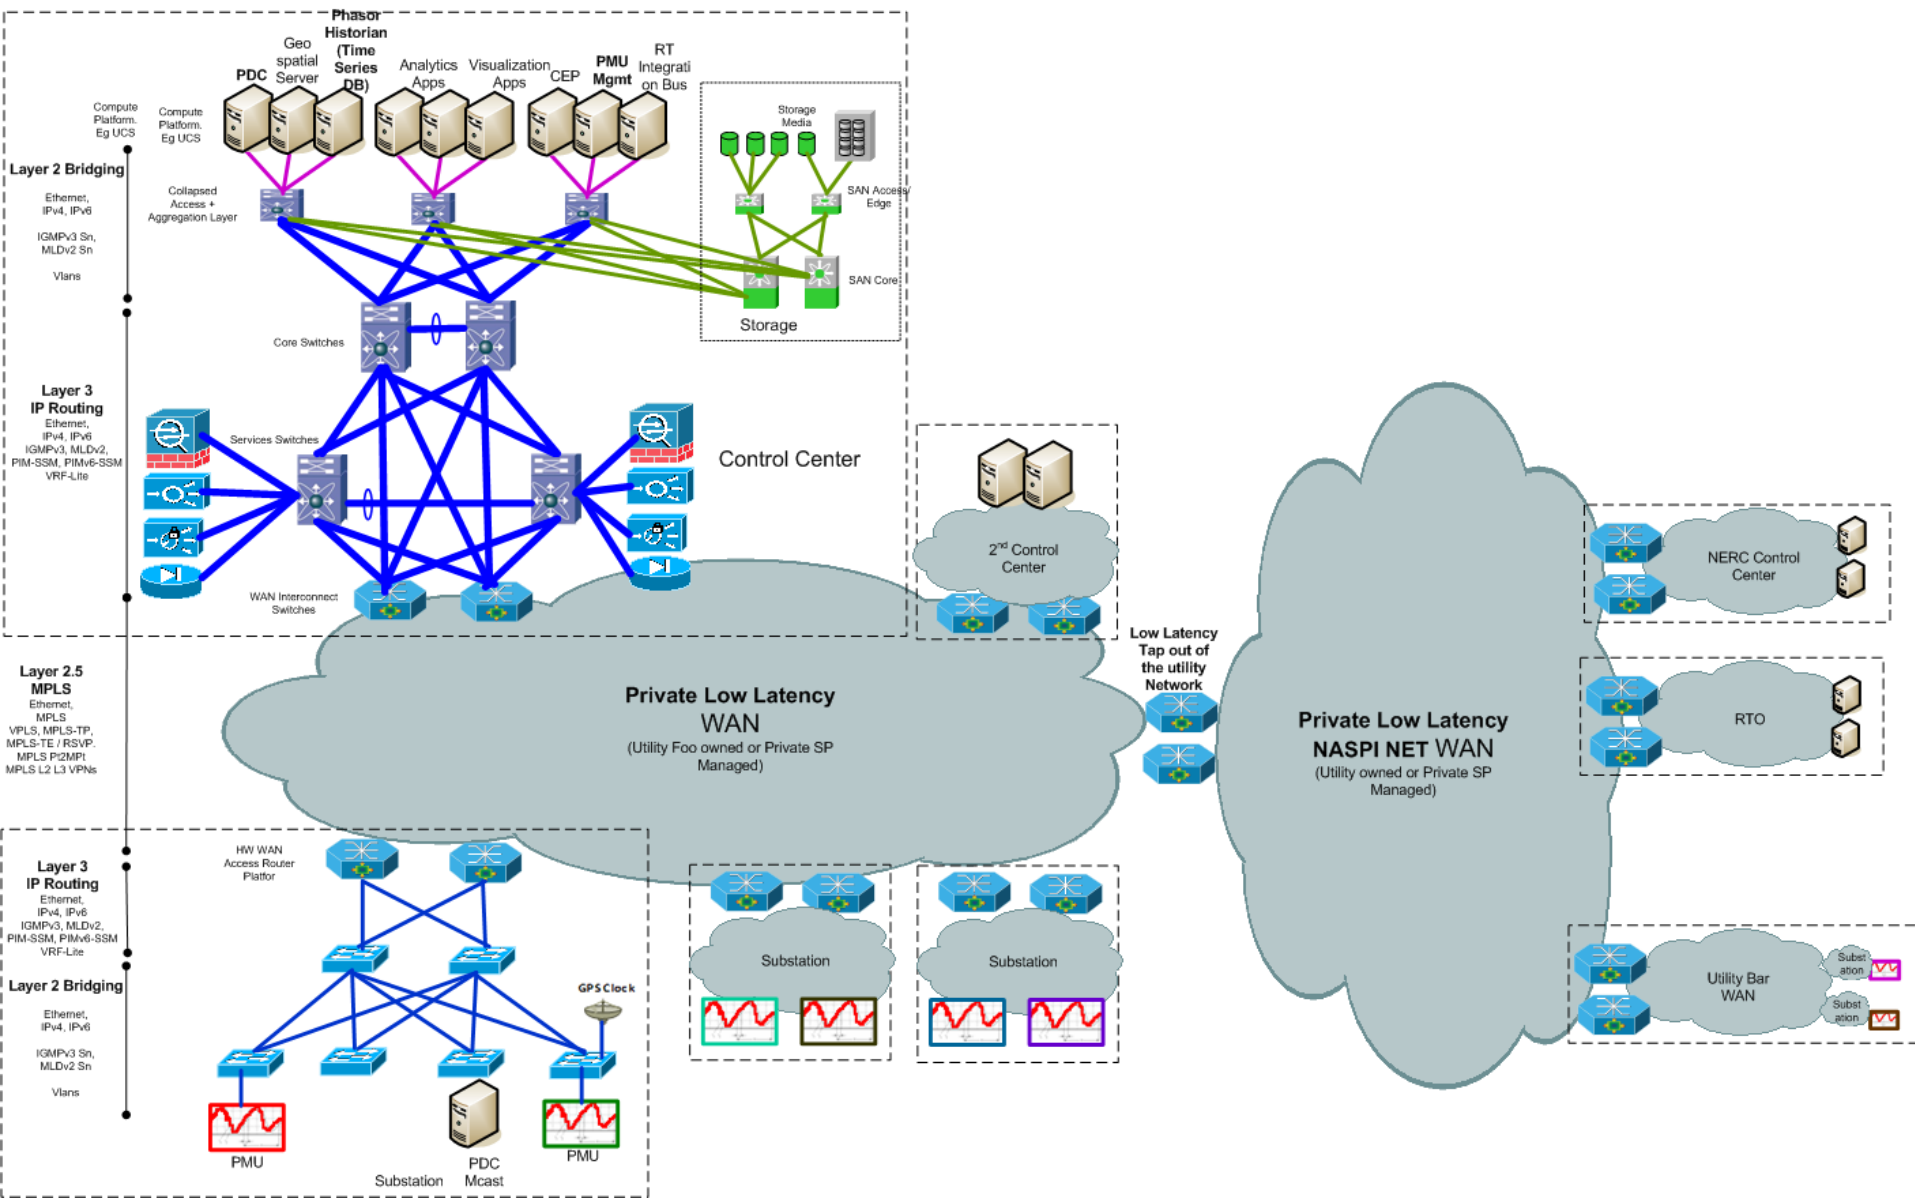

PMU Network Physical Architecture View

LEGEND

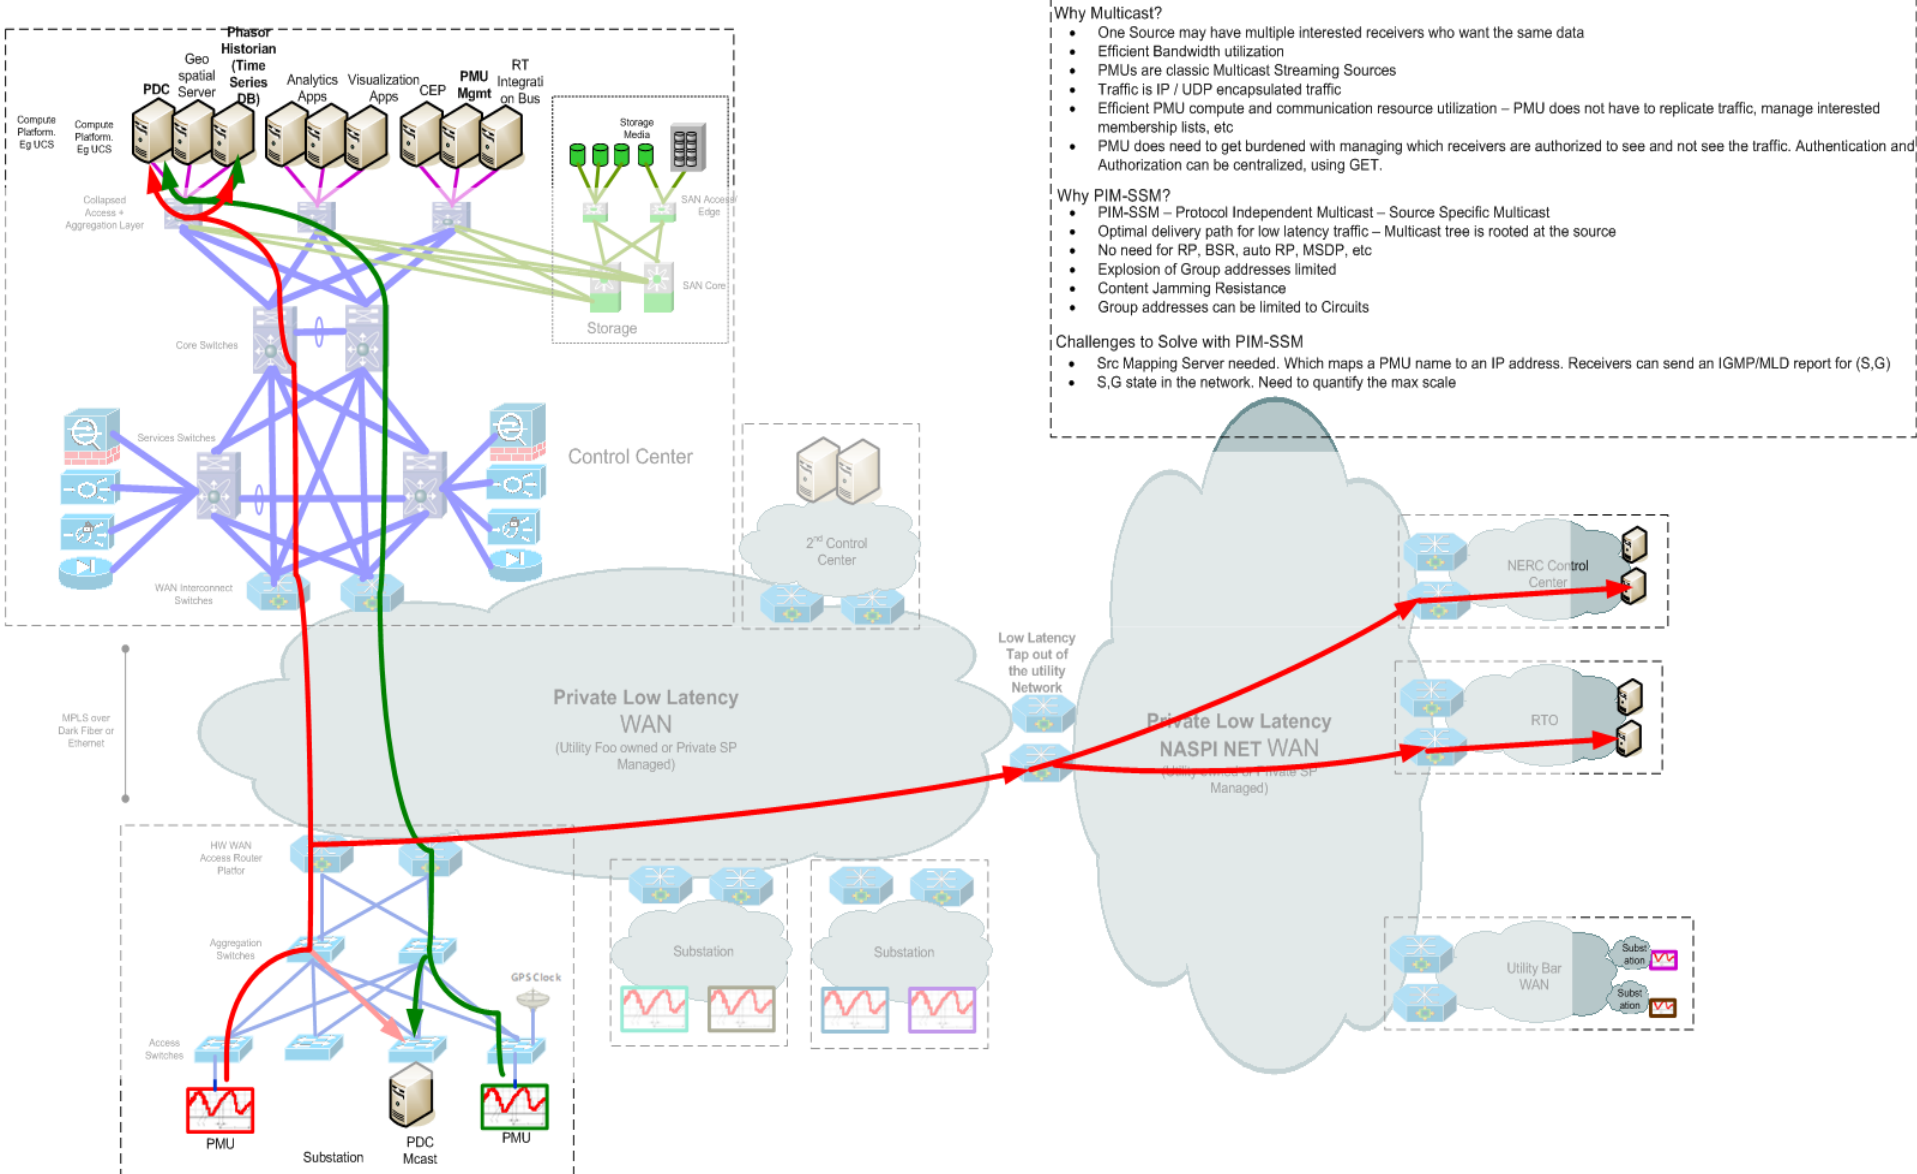

-  Fiber Channel (6G)
-  10G Ethernet Link
-  1 G Ethernet Link
-  10G FCoE, Ethernet Link
-  Port Channel

PMU Network Protocol View

Multicast for PMU Data (low, predictable latency)

Why Multicast?

- One Source may have multiple interested receivers who want the same data
- Efficient Bandwidth utilization
- PMUs are classic Multicast Streaming Sources
- Traffic is IP / UDP encapsulated traffic
- Efficient PMU compute and communication resource utilization – PMU does not have to replicate traffic, manage interested membership lists, etc
- PMU does need to get burdened with managing which receivers are authorized to see and not see the traffic. Authentication and Authorization can be centralized, using GET.

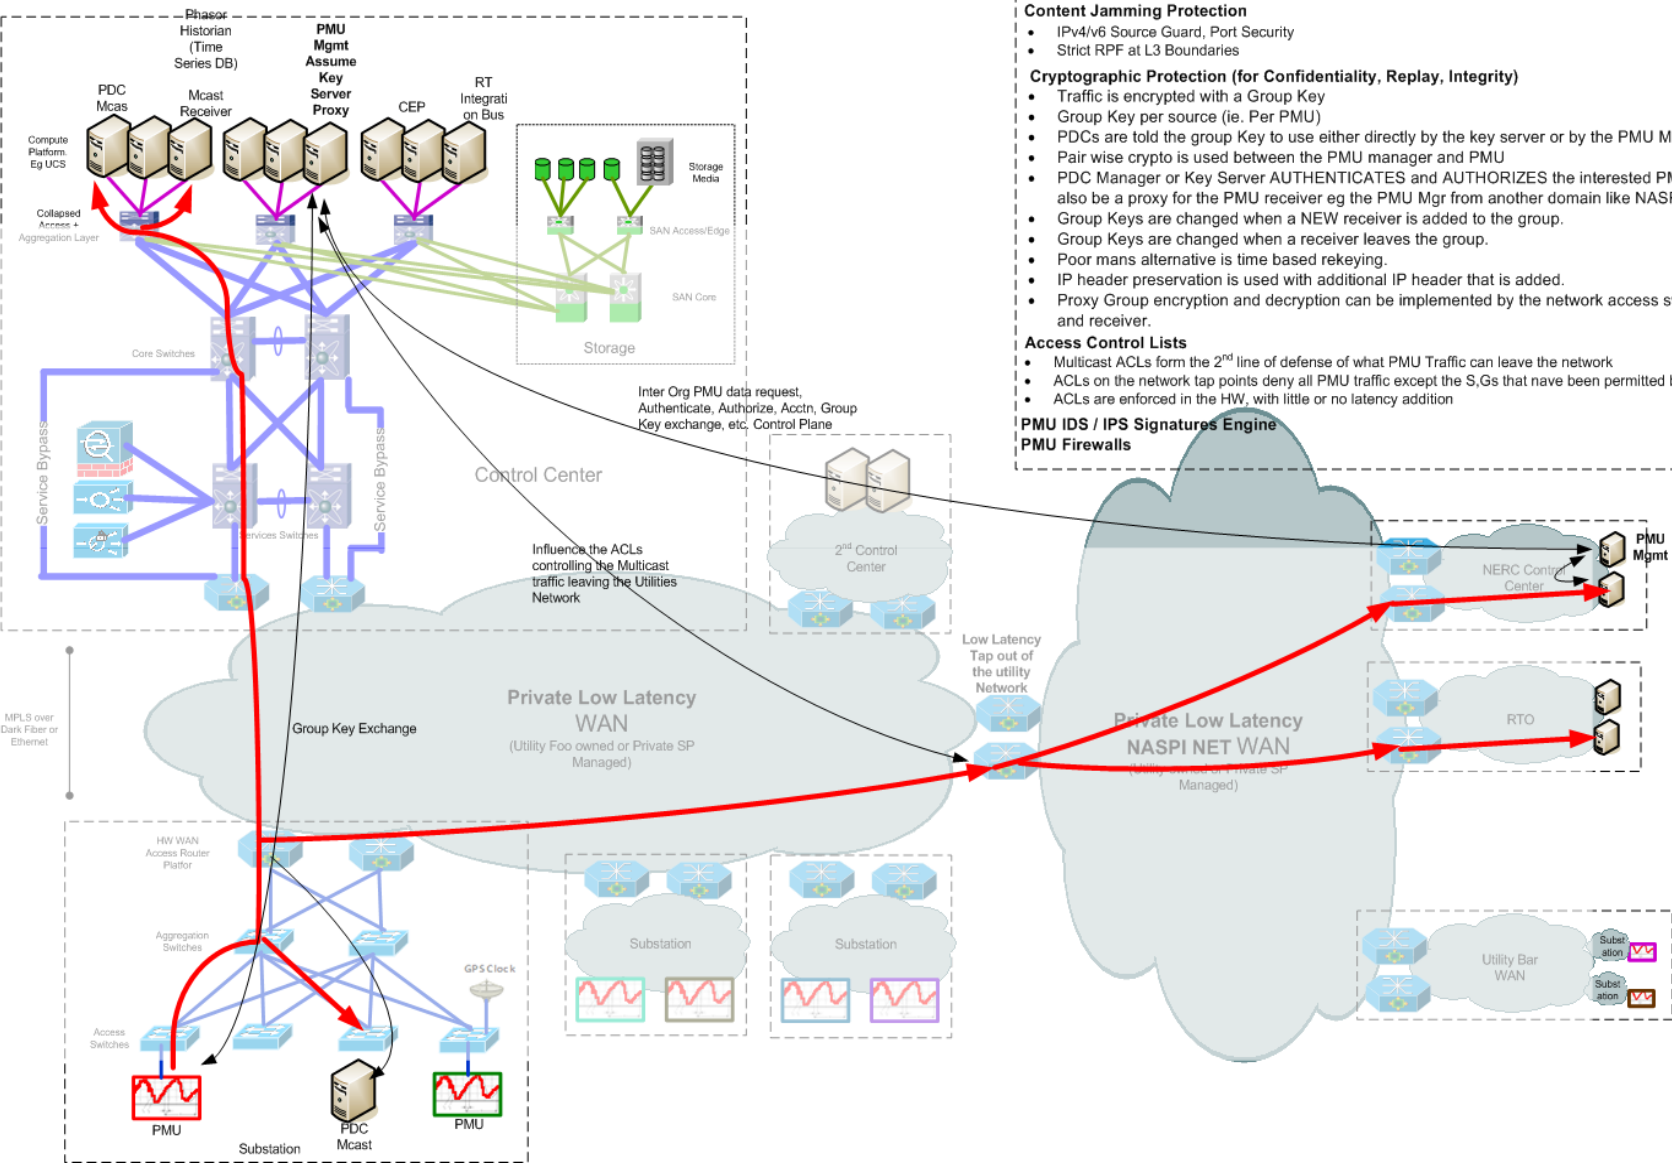

Why PIM-SSM?

- PIM-SSM – Protocol Independent Multicast – Source Specific Multicast
- Optimal delivery path for low latency traffic – Multicast tree is rooted at the source
- No need for RP, BSR, auto RP, MSDP, etc
- Explosion of Group addresses limited
- Content Jamming Resistance
- Group addresses can be limited to Circuits

Challenges to Solve with PIM-SSM

- Src Mapping Server needed. Which maps a PMU name to an IP address. Receivers can send an IGMP/MLD report for (S,G)
- S,G state in the network. Need to quantify the max scale

PMU's and Security

Security and Information Visibility

Content Jamming Protection

- IPv4/v6 Source Guard, Port Security
- Strict RPF at L3 Boundaries

Cryptographic Protection (for Confidentiality, Replay, Integrity)

- Traffic is encrypted with a Group Key
- Group Key per source (ie. Per PMU)
- PDCs are told the group Key to use either directly by the key server or by the PMU Manager App
- Pair wise crypto is used between the PMU manager and PMU
- PDC Manager or Key Server AUTHENTICATES and AUTHORIZES the interested PMU traffic receiver (it could also be a proxy for the PMU receiver eg the PMU Mgr from another domain like NASPINet-NERC-CC-PMU-Mgr)
- Group Keys are changed when a NEW receiver is added to the group.
- Group Keys are changed when a receiver leaves the group.
- Poor mans alternative is time based rekeying.
- IP header preservation is used with additional IP header that is added.
- Proxy Group encryption and decryption can be implemented by the network access switch Or by the PMU source and receiver.

Access Control Lists

- Multicast ACLs form the 2nd line of defense of what PMU Traffic can leave the network
- ACLs on the network tap points deny all PMU traffic except the S,Gs that have been permitted by the PMU Manager
- ACLs are enforced in the HW, with little or no latency addition

PMU IDS / IPS Signatures Engine PMU Firewalls

Architecture Issues

- Low Latency Communication
 - End to end hardware forwarding path
 - Application Specific Integrated Circuit (ASIC) forwarding engines
 - Predictable latency Communication
 - “Circuit like” explicit static path setup for maximum control
 - Multiple technology choices
 - MPLS-TE (Traffic Engineering)
 - MPLS-TP (Transport Profiling)
 - Predictable fail-over and network convergence
 - MPLS-TE based fast reroute
 - MPLS-TP based path protection
 - N-1 Network Redundancy
 - Predictable failover after a failure
- MPLS based core WAN network
 - MPLS is a future facing technology, which merges the best of packet switching and circuit switching
- Converged network designed to carry both IP and non IP traffic (eg IEC 61850 GOOSE) even over the WAN; extension to 61850-90-5 will enable IP/UDP-based GOOSE and SV
- Scalable Network
 - Minimizes packet replication; network replicates packets at optimal points
 - Integrates crypto without putting packet replication burden on the end host

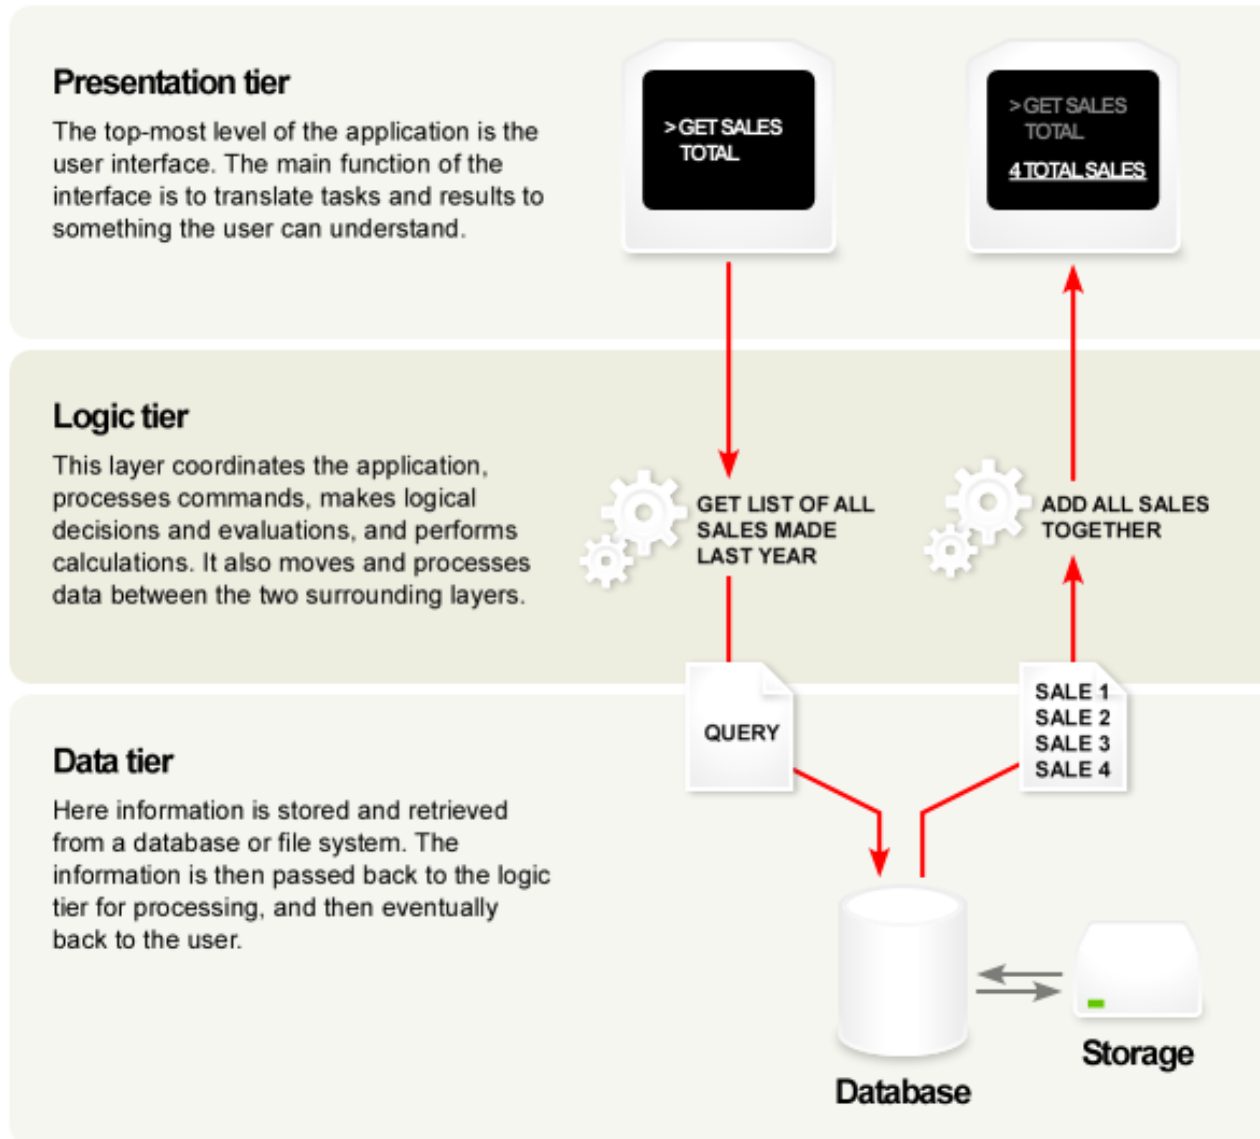

Architecture Issues, con't

- End to End QoS for low latency traffic
 - RSVP/MPLS-TE based bandwidth reservation option
 - MPLS-TP/TE based circuit setup
- Cyber security integrated into the design (rather than tagged on later)
 - Low, predictable latency security with no latency penalty
 - Anti content jamming
 - Group crypto protection for traffic
 - PMU owner controls what leaves the network via ACLs
 - PMU data traffic content can be replicated and masked by the network, as an additional service
 - Segmentation and path isolation for PMU traffic
 - PMU-based intrusion protection

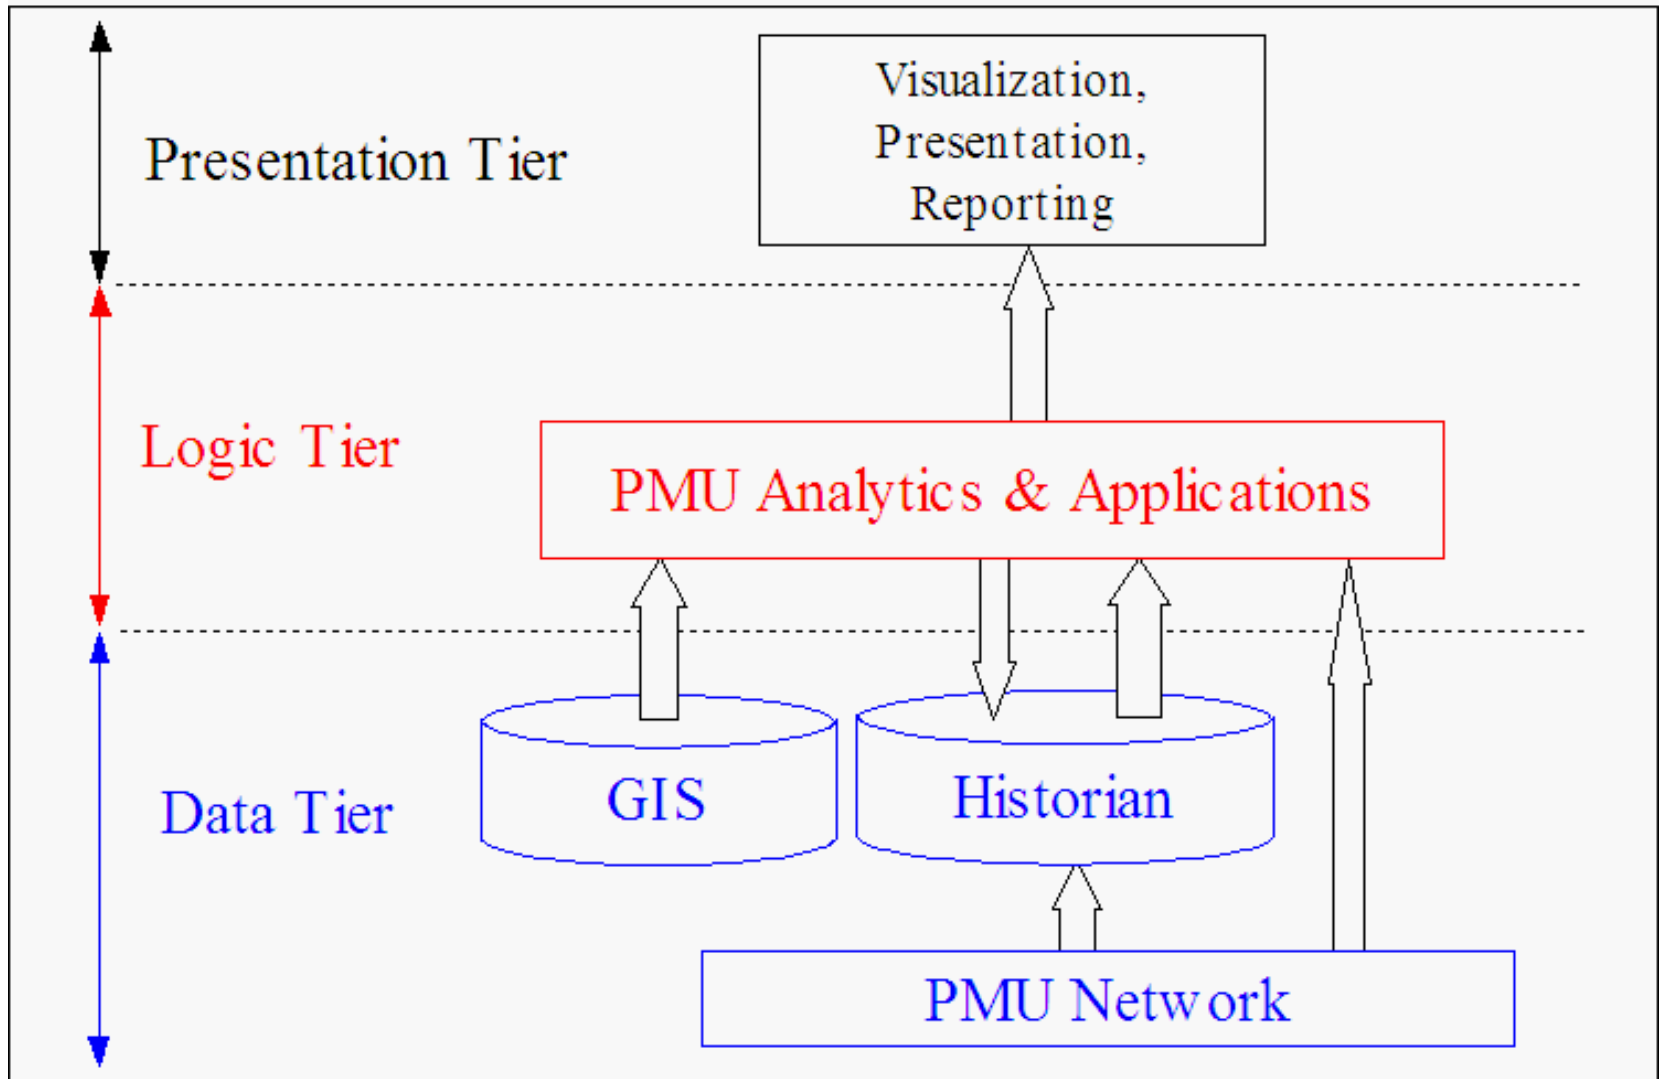

Monitoring Center Architecture

- Use modified version of existing three tier architecture
- Make maximum use of network since it must be present anyway
- Avoid data concentrator stacking
- Minimize use of physical gateways

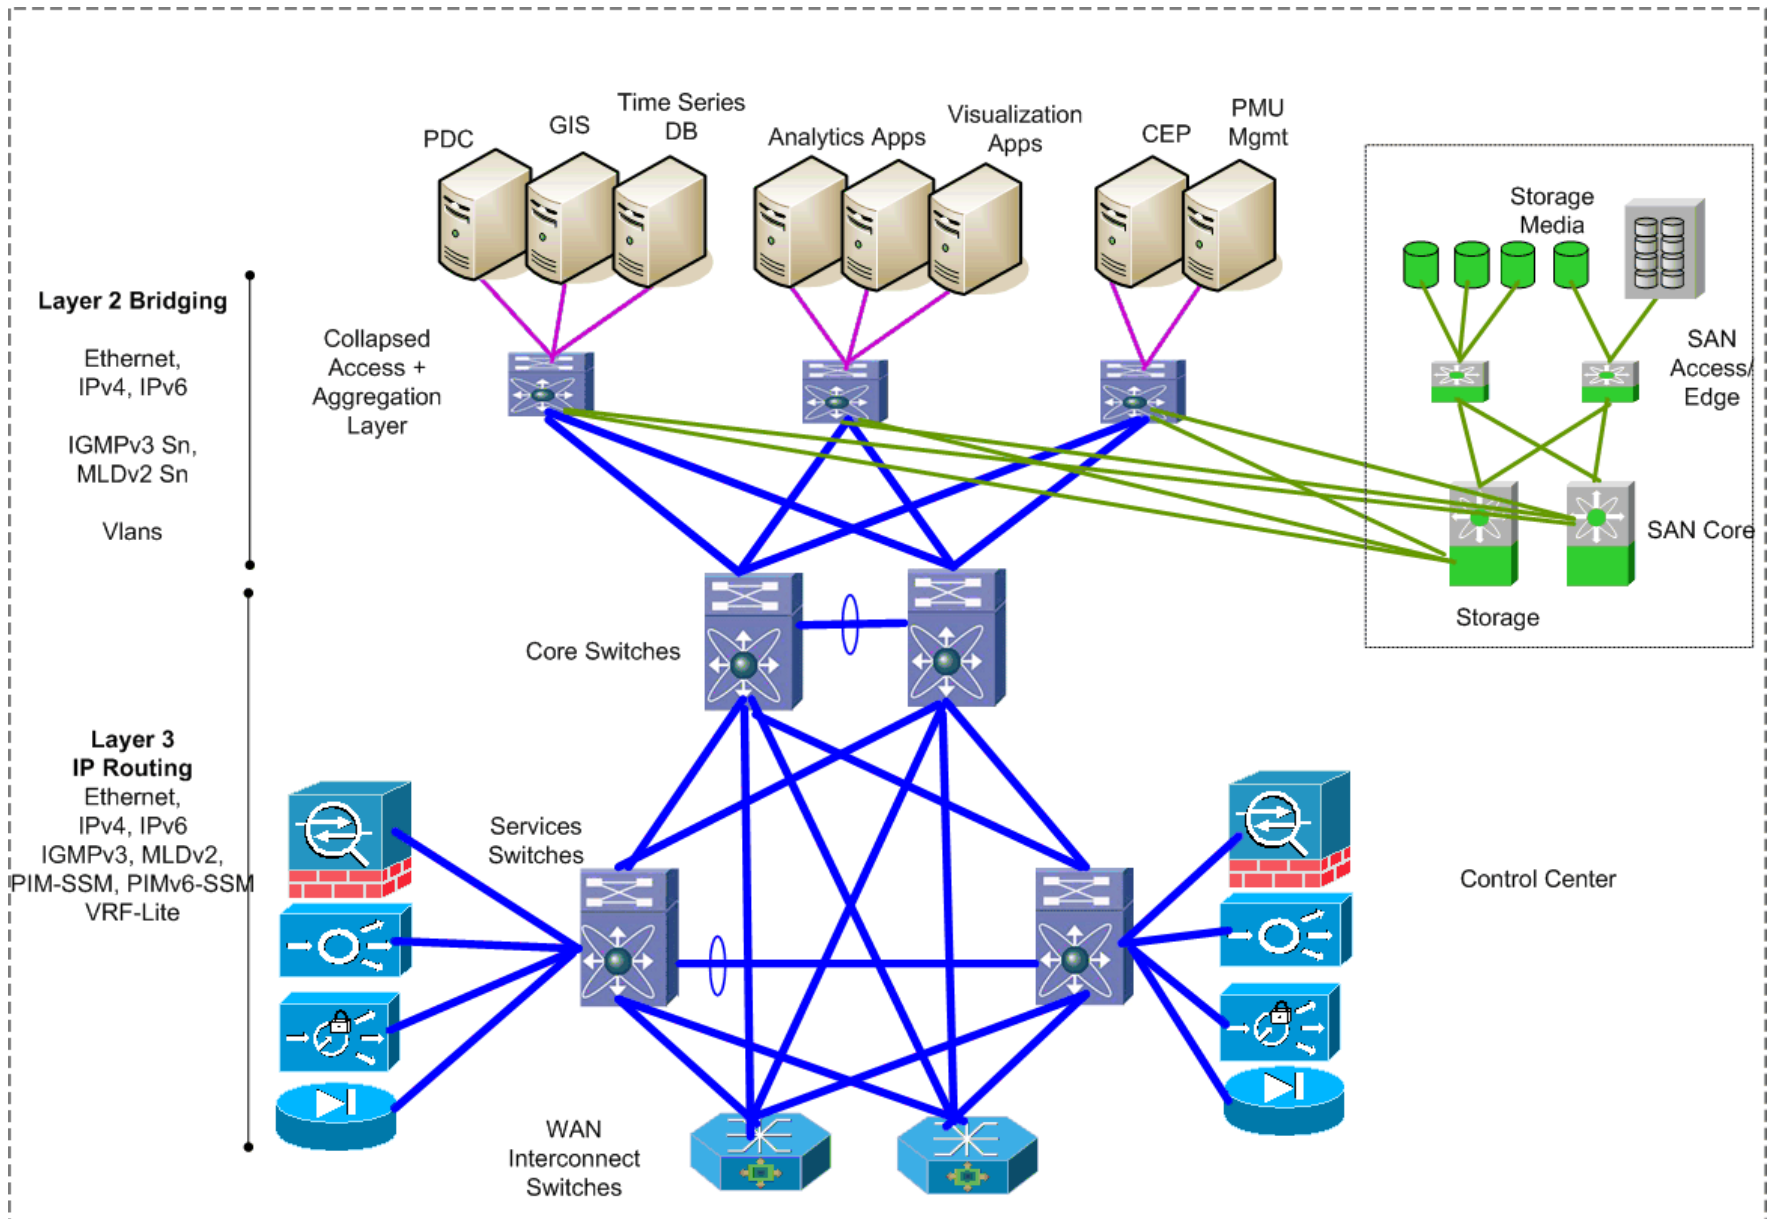

Standard Three Tier Architecture

Three Tier PMU Analytics Architecture

Monitoring Center Technical Architecture Example

PMU Gateways and Data Concentration

- Convert PDC and PDG boxes to service abstractions
- Virtualize services and distribute as needed via Service Insertion
- Allow services to reside where needed:
 - Dedicated server
 - Historian
 - Application
 - Network
- Put concentration elements in parallel near applications to avoid stacking
- Workflow management via Service Insertion Architecture and application design

Conclusions/Recommendations

- Implement engineered PMU networks using COTS networking gear
- Use standard protocols and well established methods for security, QoS
- Use the network to maximum advantage since it must be there anyway
 - Advanced architecture based on standard protocols
 - Service abstraction, virtualization, service insertion
- Clean application suite architecture
- Provide forward path compatibility (future-proofing)
- Extension paths for additional complexity where utilities desire it
