Outline

- ▣ Description of the Event
- ▣ Event Propagation Movie
- ▣ Disturbance Data Analysis
 - Modal Analysis from Power Signals
 - Modal Analysis of Voltage Angle Oscillations
- ▣ Ambient Data - Spectral Analysis of Power and Frequency Signals
- ▣ Conclusions

Event Description

- ➡ Disturbance was initiated by a failure on a 138 kV switch.
- ➡ Local primary protection and local back-up breaker failure protection was disabled for troubleshooting
- ➡ Remote backup protection relays performed delayed clearing of the 138 kV fault (1ϕ fault evolved into 3ϕ fault)
- ➡ Disturbance outcome (FRCC Report):
 - 25 transmission lines tripped - involved in remote clearing
 - Generation loss: $\approx 2,500$ MW near fault + 1,800 MW across FRCC
 - Load shedding: 2,300 MW for initial fault clearing
 - Under-Frequency Load Shedding: 2,200 MW between UFLS zones in FL (other regions did not participate in UFLS)
 - Other: delayed clearing produced low voltages; two nuclear units tripped as designed
- ➡ Noticable interarea oscillations in the EI \Rightarrow for our analysis

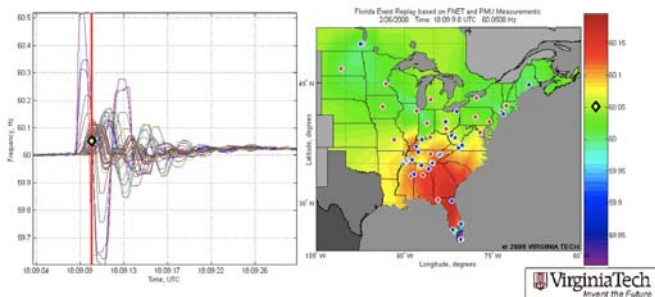

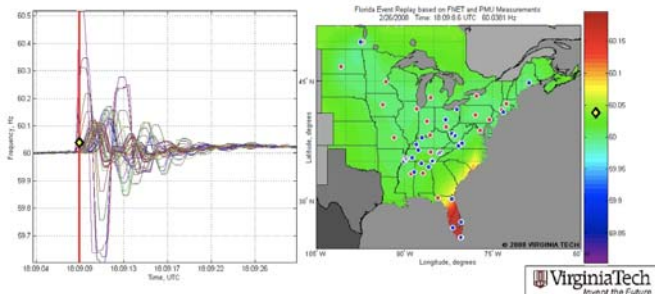

Available PMU Data

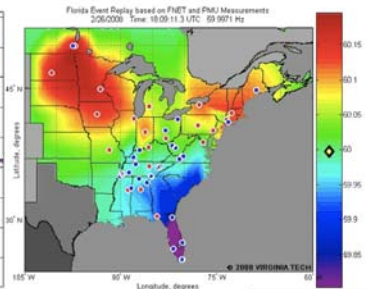

- Unavailable data from NY due to communication upgrades, some data loss from several other regions.

Modal Analysis from Active Power Signals

- How are the modes propagated across the network?
- Analyze the power oscillations in different points of the EI.
 - Power oscillations from each mode indicate how the disturbance is being propagated.
- Shelby and Freeport are very close to Cordova.

Identified Modes from Power Oscillations

- Two oscillatory frequencies: $f_1 = 0.22$ Hz with $\zeta_1 = 15.97$ %, and $f_2 = 0.49$ Hz with $\zeta_2 = 8.6$ %

ERA Approximation of Active Powers at Orrington, Duval, and Dorsey

PMU Measurements and Frequency Components from ERA Approximation

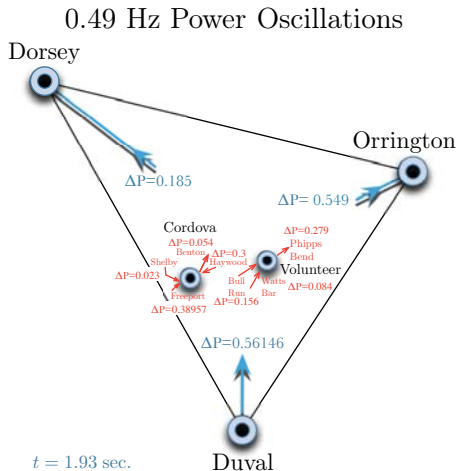

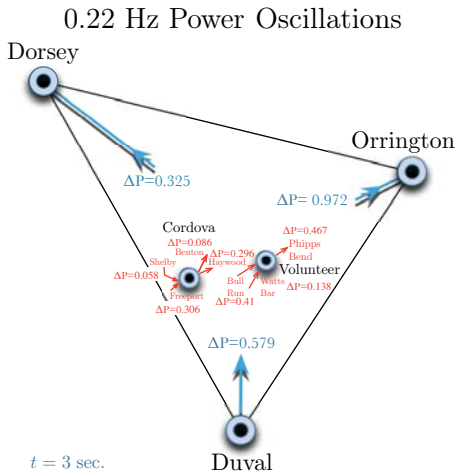

Cordova PMU Measurements and Frequency Components from ERA Approximation

Active Power Oscillations of 0.22 Hz and 0.49 Hz

Propagation of 0.22 Hz and 0.49 Hz Power Oscillations

Simultaneous identification of Interarea Modes using Voltage Angle and Magnitude

PMU Measurements and Frequency Components from ERA Approximation

Voltage Angles

Voltage Magnitudes

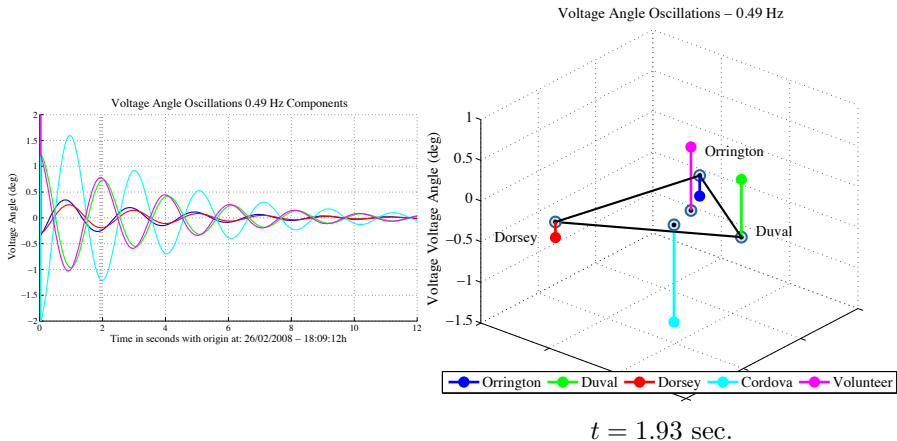

0.22 Hz Oscillations in the Voltage Angles - Modeshape

$t = 3$ sec.

0.49 Hz Oscillations in the Voltage Angles - Modeshape

Spectral Analysis of Power Signals

- Two oscillatory frequencies: $f_1 = 0.2 - 0.3$ Hz and $f_2 = 0.45$ Hz

Periodograms of Active Powers at Orrington, Duval, and Dorsey

Zoomed image representation of Weighted Periodogram

15 minute frames - 150 second segments - 50% overlap - Half-Sine Weighting Function

Conclusions

- ➡ Oscillatory modes using bus angle and line active power can be used to trace propagation of interarea modes.
- ➡ Disturbance Data
 - 0.22 Hz mode - Duval vs Orrington & Dorsey (South vs North)
 - 0.49 Hz mode - More complex mode shape (caterpillar type)
- ➡ Ambient Data
 - 0.45 Hz mode - Persistent (light damping)
 - ≈ 0.2 -0.3 Hz mode - not visible in JF and BRun Frequency (pivot of the system)
